Introduction

Combinatorics

Geometry
A (Kac-Moody) root system $\Phi$ defines a group $W$ of transformations, generated by the reflections orthogonal (in the sense of the symmetric bilinear form $K$) to the simple roots. This naturally gives $W$ the structure of a Coxeter group.

Coxeter groups are defined abstractly within the framework of combinatorial group theory. That is, we are given a presentation of a group by generators and relations.

The abstract algebra encodes the geometry surprisingly well: Not only does each root system define a Coxeter group, but also each Coxeter group can be represented geometrically by specifying a root system.

Coxeter groups are defined abstractly within the framework of combinatorial group theory. That is, we are given a presentation of a group by generators and relations.

The abstract algebra encodes the geometry surprisingly well: Not only does each root system define a Coxeter group, but also each Coxeter group can be represented geometrically by specifying a root system.

But we need a root system given by a “generalized” generalized Cartan matrix for a “non-crystallographic” Coxeter group.
In this lecture, we’ll provide some basic background on Coxeter groups that will be useful for understanding Cambrian lattices and sortable elements.

Standard references include (BB), (B), and (H).

A summary, written specifically for use with sortable elements and Cambrian lattices, can be found in Section 2 of (INF).
A Coxeter group is a group with a certain presentation. Choose a finite generating set \( S = \{s_1, \ldots, s_n\} \) and for every \( i < j \), choose an integer \( m(i, j) \geq 2 \), or \( m(i, j) = \infty \). Define:

\[
\mathcal{W} = \left\langle S \mid s_i^2 = 1, \ \forall \ i \ \text{and} \ (s_is_j)^{m(i,j)} = 1, \ \forall \ i < j \right\rangle.
\]

$$W = \langle S \mid s_i^2 = 1, \forall i \quad \text{and} \quad (s_i s_j)^{m(i,j)} = 1, \forall i < j \rangle.$$ 

Why would anyone write this down?

Why would anyone write this down?

Exercise 4Ba

Let $\Phi$ be a Kac-Moody root system with simple roots $\Pi = \{\alpha_1, \ldots, \alpha_n\}$ and define $S = \{s_1, \ldots, s_n\}$ for $s_i$ as in Lecture 3B. Define $m(i, j)$ to be $\frac{2\pi}{\pi - \text{angle}(\alpha_i, \alpha_j)}$. Show that the group $W'$ generated by $S$ satisfies the relations given above.

The exercise shows that $W'$ is a homomorphic image of the abstract Coxeter group $W$. In fact, the two are isomorphic. Thus all of our root systems examples yield Coxeter group examples.
We’ll focus on two examples:

- The dihedral group of order 8:

\[ B_2 = \langle \{s_1, s_2\} \mid s_1^2 = s_2^2 = (s_1 s_2)^4 = 1 \rangle. \]

This is the Coxeter group associated to the root system \( B_2 \). Its elements are

\[ 1, s_1, s_2, s_1s_2, s_2s_1, s_1s_2s_1, s_2s_1s_2, s_1s_2s_1s_2 = s_2s_1s_2s_1. \]
Coxeter group examples

We’ll focus on two examples:

- The dihedral group of order 8:
  \[ B_2 = \langle \{s_1, s_2\} \mid s_1^2 = s_2^2 = (s_1 s_2)^4 = 1 \rangle. \]
  This is the Coxeter group associated to the root system \( B_2 \).
  Its elements are
  
  \[ 1, s_1, s_2, s_1 s_2, s_2 s_1, s_1 s_2 s_1, s_2 s_1 s_2, s_1 s_2 s_1 s_2 = s_2 s_1 s_2 s_1. \]

- The symmetric group \( S_{n+1} \) (AKA \( A_n \)):
  This is the group of permutations of \([n + 1]\). Writing \( s_i = (i \ i + 1) \), the symmetric group is a Coxeter group with
  
  \[ m(i, j) = \begin{cases} 
  3 & \text{if } j = i + 1, \text{ or} \\
  2 & \text{if } j > i + 1. 
  \end{cases} \]
  This is the Coxeter group associated to the root system \( A_n \),
  constructed explicitly as \( \{e_j - e_i : i, j \in [n + 1], i \neq j\} \) in
  Exercise 1k.1. This construction leads to a representation of
  \( S_{n+1} \) as permutations of the coordinates.
The Coxeter diagram of a Coxeter system \((W, S)\) is a graph with

- Vertex set: \(\{1, \ldots, n\}\).
- Edges: \(i \leftrightarrow j\) if \(m(i, j) \geq 3\).
- Edge labels: \(m(i, j)\). By convention, we omit edge labels “3.”

The dihedral group of order 8 has a diagram with two vertices connected by an edge labeled 4.

The diagram for \(A_n\) is

```
. . . .
```

Obs: Non-edges \(\Leftrightarrow m(i, j) = 2 \Leftrightarrow s_i\) and \(s_j\) commute.
The set $S$ is called the **simple reflections**. The set

$$T = \{ wsw^{-1} : w \in W, s \in S \}$$

is called the set of **reflections** in $W$. Why?

**Exercise 4Bb**

*Suppose that $W$ is the (Coxeter) group defined (under the name $W'$) in Exercise 4Ba. Show that*

1. *For every reflection $t \in T$, there is a unique positive root $\beta \in \Phi_+$ such that $t$ is the reflection orthogonal to $t$ (in the sense of $K$).*

2. *For every root $\beta$, the reflection orthogonal to $t$ (in the sense of $K$) is an element of $T$.*

Thus, reflections are in bijection with positive roots! We’ll write $\beta_t$ for the positive root associated with $t \in T$. Furthermore, $T$ is the complete set of elements of $W$ that act as reflections.
Reflections in $B_2$ and $A_n$

$B_2$:

$S = \{s_1, s_2\}$
$T = \{s_1, s_2, s_1 s_2 s_1, s_2 s_1 s_2\}$

There are 4 positive roots.

$A_n = S_{n+1}$:

$S = \{\text{adjacent transpositions } (i \ i+1)\}$
$T = \{\text{all transpositions } (i \ j)\}$

The positive roots are $\{e_j - e_i : i, j \in [n + 1], i < j\}$
(Exercise 1m.1).
Reduced words and the word problem

Since $W$ is generated by $S$, each element $w$ of $W$ can be written (in many ways!) as a word in the “alphabet” $S$.

A word of minimal length, among words for $w$, is called a reduced word for $w$.

The length $\ell(w)$ of $w$ is the length of a reduced word for $w$.

Solution to the word problem for $W$ (J. Tits):

Any word for $w$ can be converted to a reduced word for $w$ by a sequence of

- braid moves: $s_is_j\ldots \leftrightarrow s_js_is_j\ldots$ ($m(i,j)$ letters)
- nil moves: delete $s_is_i$.

Any two reduced words for $w$ are related by a sequence of braid moves.

Exercise 4Bc

Find all reduced words for $4321 \in S_4$. 
An inversion of $w \in W$ is a reflection $t \in T$ such that $\ell(tw) < \ell(w)$. The notation $\text{inv}(w)$ means \{inversions of $w$\}.

If $a_1 \cdots a_k$ is a reduced word for $w$, then write $t_i = a_1 \cdots a_i \cdots a_1$.

$$\text{inv}(w) = \{t_i : 1 \leq i \leq k\}.$$ 

The sequence $t_1, \ldots, t_k$ is the reflection sequence for the reduced word $a_1 \cdots a_k$. 
The **weak order** on a Coxeter group $W$ sets $u \leq w$ if and only if a reduced word for $u$ occurs as a prefix of some reduced word for $w$. The covers are $w < ws$ for $w \in W$ and $s \in S$ with $\ell(w) < \ell(ws)$. Equivalently, $u \leq w$ if and only if $\text{inv}(u) \subseteq \text{inv}(w)$.

**Example:**

$$B_2 = \langle \{s_1, s_2\} \mid s_1^2 = s_2^2 = (s_1 s_2)^4 = 1 \rangle$$

The weak order is ranked by the length function $\ell$. It is a **meet semilattice** in general, and a **lattice** when $W$ is finite.
Weak order (Right weak order)

The weak order on a Coxeter group $W$ sets $u \leq w$ if and only if a reduced word for $u$ occurs as a prefix of some reduced word for $w$.

The covers are $w < ws$ for $w \in W$ and $s \in S$ with $\ell(w) < \ell(ws)$.

Equivalently, $u \leq w$ if and only if $\text{inv}(u) \subseteq \text{inv}(w)$.

**Example:**

$$B_2 = \langle \{s_1, s_2\} \mid s_1^2 = s_2^2 = (s_1 s_2)^4 = 1 \rangle$$

The weak order is ranked by the length function $\ell$.

It is a meet semilattice in general, and a lattice when $W$ is finite.

**Alert:** This is “right” weak order. There is also a “left” weak order.
Inversions and weak order in $S_{n+1}$

We will write a permutation $\pi$ in one-line notation $\pi_1 \cdots \pi_{n+1}$. Then the cover relations in the weak order are transpositions of adjacent entries. Going “up” means putting the entries out of numerical order.

The weak order on $S_3$:

```
321
/  \
312 231
/ \\/
132 213
/     /
123
```

Inversions are

$$\text{inv}(\pi) = \{\text{transpositions } (i \ j) : i \text{ comes before } j \text{ in } \pi\},$$

and this is the origin of the term “inversion.”
The weak order on $S_4$
A cover reflection of $w \in W$ is an inversion $t$ of $w$ such that $tw = ws$ for some $s \in S$.

The name “cover reflection” refers to the fact that $w$ covers $tw$ in the weak order.

Indeed, for each cover $ws \prec w$, there is a cover reflection $wsw^{-1}$ of $w$.

The set of cover reflections of $w$ is written $\text{cov}(w)$.

In $S_{n+1}$:

$$\text{cov}(\pi) = \{\text{transpositions } (i \ j) : i \text{ immediately before } j \text{ in } \pi\}.$$
Bringing geometry into the picture

Exercise 4Bd

Show that the diagram of a Coxeter system associated to a Kac-Moody root system has the following properties.

1. Each edge is unlabeled or has label 4, 6 or $\infty$.
2. Any cycle has an even number of 4’s and an even number of 6’s.

Exercise 4Be

Given a Coxeter group $W$ whose diagrams satisfy the conditions of Exercise 4Bd, show that there is a Kac-Moody root system associated to $W$.

In fact, there are many!

In general, we can make a “generalized” generalized Cartan matrix and root system for any Coxeter group if we allow non-integer entries and add an additional technical condition.
The Tits cone

Define

\[ D = \bigcap_{\alpha_i \in \Pi} \{ x \in V^* : \langle x, \alpha_i \rangle \geq 0 \} \]

This is an \( n \)-dimensional simplicial cone in the dual space \( V^* \).

The set \( \mathcal{F}(A) \) of all cones \( wD \) and their faces is a fan in \( V^* \) which we call the Coxeter fan. Its maximal cones are in bijection with elements of \( W \) (i.e. the map \( w \mapsto wD \) is injective).

The union of the cones of \( \mathcal{F}(A) \) is a convex subset of \( V^* \) known as the Tits cone and denoted \( \text{Tits}(A) \).

The cones \( wD \) are the regions in \( \text{Tits}(A) \) defined by the reflecting hyperplanes \( \{ \beta^\perp : \beta \in \Phi \} \).
Tits cone example: $B_2$

$$D = \bigcap_{\alpha_i \in \Pi} \{ x \in V^* : \langle x, \alpha_i \rangle \geq 0 \}$$

In this case, Tits$(A)$ is all of $V^*$. We’ll label each region $wD$ by $w$. 
Tits cone example: $B_2$

$$D = \bigcap_{\alpha_i \in \Pi} \{ x \in V^* : \langle x, \alpha_i \rangle \geq 0 \}$$

In this case, Tits(A) is all of $V^*$. We’ll label each region $wD$ by $w$. 

![Diagram](image.png)
Tits cone example: $B_2$

\[ D = \bigcap_{\alpha_i \in \Pi} \{ x \in V^* : \langle x, \alpha_i \rangle \geq 0 \} \]

In this case, Tits(A) is all of $V^*$. We’ll label each region $wD$ by $w$.

\[ * = s_1 s_2 s_1 s_2 = s_2 s_1 s_2 s_1 \]
Tits cone example: $S_4$

Blue region is $D$.

Again, Tits($A$) is all of $V^*$

Largest circles: hyperplanes for $s_1$, $s_2$, and $s_3$. ($s_2$ on top.)
